22-1 What is Physics?

The physics of the preceding chapter tells us how to find the electric force on a particle 1 of charge $+q_1$ when the particle is placed near a particle 2 of charge $+q_2$. A nagging question remains: How does particle 1 “know” of the presence of particle 2? That is, since the particles do not touch, how can particle 2 push on particle 1—how can there be such an action at a distance?

One purpose of physics is to record observations about our world, such as the magnitude and direction of the push on particle 1. Another purpose is to provide a deeper explanation of what is recorded. One purpose of this chapter is to provide such a deeper explanation to our nagging questions about electric force at a distance. We can answer those questions by saying that particle 2 sets up an electric field in the space surrounding itself. If we place particle 1 at any given point in that space, the particle “knows” of the presence of particle 2 because it is affected by the electric field that particle 2 has already set up at that point. Thus, particle 2 pushes on particle 1 not by touching it but by means of the electric field produced by particle 2.

Our goal in this chapter is to define electric field and discuss how to calculate it for various arrangements of charged particles.

22-2 The Electric Field

The temperature at every point in a room has a definite value. You can measure the temperature at any given point or combination of points by putting a thermometer there. We call the resulting distribution of temperatures a temperature field. In much the same way, you can imagine a pressure field in the atmosphere; it consists of the distribution of air pressure values, one for each point in the atmosphere. These two examples are of scalar fields because temperature and air pressure are scalar quantities.

The electric field is a vector field; it consists of a distribution of vectors, one for each point in the region around a charged object, such as a charged rod. In principle, we can define the electric field at some point near the charged object, such as point $P$ in Fig. 22-1a, as follows: We first place a positive charge $q_0$, called a test charge, at the point. We then measure the electrostatic force $\vec{F}$ that acts on the test charge. Finally, we define the electric field $\vec{E}$ at point $P$ due to the charged object as

\begin{equation}
(22-1)
\end{equation}
Thus, the magnitude of the electric field \( \vec{E} \) at point \( P \) is \( E = \frac{F}{q_0} \), and the direction of \( \vec{E} \) is that of the force \( \vec{F} \) that acts on the positive test charge. As shown in Fig. 22-1b, we represent the electric field at \( P \) with a vector whose tail is at \( P \). To define the electric field within some region, we must similarly define it at all points in the region.

![Figure 22-1](a) A positive test charge \( q_0 \) placed at point \( P \) near a charged object. An electrostatic force \( \vec{F} \) acts on the test charge. (b) The electric field \( \vec{E} \) at point \( P \) produced by the charged object.

The SI unit for the electric field is the newton per coulomb (N/C). Table 22-1 shows the electric fields that occur in a few physical situations.

Although we use a positive test charge to define the electric field of a charged object, that field exists independently of the test charge. The field at point \( P \) in Figure 22-1b existed both before and after the test charge of Fig. 22-1a was put there. (We assume that in our defining procedure, the presence of the test charge does not affect the charge distribution on the charged object, and thus does not alter the electric field we are defining.)

To examine the role of an electric field in the interaction between charged objects, we have two tasks: (1) calculating the electric field produced by a given distribution of charge and (2) calculating the force that a given field exerts on a charge placed in it. We perform the first task in Sections 22-4 through 22-7 for several charge distributions. We perform the second task in Sections 22-8 and 22-9 by considering a point charge and a pair of point charges in an electric field. First, however, we discuss a way to visualize electric fields.

---

**Electric Field Lines**

Michael Faraday, who introduced the idea of electric fields in the 19th century, thought of the space around a charged body as filled with *lines of force*. Although we no longer attach much reality to these lines, now usually called **electric field lines**, they still provide a nice way to visualize patterns in electric fields.

The relation between the field lines and electric field vectors is this: (1) At any point, the direction of a straight field line or the direction of the tangent to a curved field line gives the direction of \( \vec{E} \) at that point, and (2) the field lines are drawn so that the number of lines per unit area, measured in a plane that is perpendicular to the lines, is proportional to the magnitude of \( \vec{E} \). Thus, \( E \) is large where field lines are close together and small where they are far apart.

Figure 22-2a shows a sphere of uniform negative charge. If we place a *positive* test charge anywhere near the sphere, an electrostatic force pointing *toward* the center of the sphere will act on the test charge as shown. In other words, the electric field vectors at all points near the sphere are directed radially toward the sphere. This pattern of vectors is neatly displayed by the field lines in Fig. 22-2b, which point in the same directions as the force and field vectors. Moreover, the spreading of the field lines with distance from the sphere tells us that the magnitude of the electric field decreases with distance from the sphere.
Figure 22-2

(a) The electrostatic force $\vec{F}$ acting on a positive test charge near a sphere of uniform negative charge. (b) The electric field vector $\vec{E}$ at the location of the test charge, and the electric field lines in the space near the sphere. The field lines extend toward the negatively charged sphere. (They originate on distant positive charges.)

If the sphere of Fig. 22-2 were of uniform positive charge, the electric field vectors at all points near the sphere would be directed radially away from the sphere. Thus, the electric field lines would also extend radially away from the sphere. We then have the following rule:

Electric field lines extend away from positive charge (where they originate) and toward negative charge (where they terminate).

Figure 22-3a shows part of an infinitely large, nonconducting sheet (or plane) with a uniform distribution of positive charge on one side. If we were to place a positive test charge at any point near the sheet of Fig. 22-3a, the net electrostatic force acting on the test charge would be perpendicular to the sheet, because forces acting in all other directions would cancel one another as a result of the symmetry. Moreover, the net force on the test charge would point away from the sheet as shown. Thus, the electric field vector at any point in the space on either side of the sheet is also perpendicular to the sheet and directed away from it (Figs. 22-3b and c). Because the charge is uniformly distributed
along the sheet, all the field vectors have the same magnitude. Such an electric field, with the same magnitude and direction at every point, is a uniform electric field.

**Figure 22-3**

(a) The electrostatic force \( \vec{F} \) on a positive test charge near a very large, nonconducting sheet with uniformly distributed positive charge on one side. (b) The electric field vector \( \vec{E} \) at the location of the test charge, and the electric field lines in the space near the sheet. The field lines extend away from the positively charged sheet. (c) Side view of (b).

Of course, no real nonconducting sheet (such as a flat expanse of plastic) is infinitely large, but if we consider a region that is near the middle of a real sheet and not near its edges, the field lines through that region are arranged as in Figs. 22-3b and c.

Figure 22-4 shows the field lines for two equal positive charges. Figure 22-5 shows the pattern for two charges that are equal in magnitude but of opposite sign, a configuration that we call an electric dipole. Although we do not often use field lines quantitatively, they are very useful to visualize what is going on.

**Figure 22-4** Field lines for two equal positive point charges. The charges repel each other. (The lines terminate on distant negative charges.) To “see” the actual three-dimensional pattern of field lines, mentally rotate the pattern shown here about an axis passing through both charges in the plane of the page. The three-dimensional pattern and the electric field it represents are said to have rotational symmetry.
about that axis. The electric field vector at one point is shown; note that it is tangent to the field line through that point.

![Figure 22-5](image_url)

Field lines for a positive point charge and a nearby negative point charge that are equal in magnitude. The charges attract each other. The pattern of field lines and the electric field it represents have rotational symmetry about an axis passing through both charges in the plane of the page. The electric field vector at one point is shown; the vector is tangent to the field line through the point.

---

**The Electric Field Due to a Point Charge**

To find the electric field due to a point charge \( q \) (or charged particle) at any point a distance \( r \) from the point charge, we put a positive test charge \( q_0 \) at that point. From Coulomb’s law (Eq. 21-1), the electrostatic force acting on \( q_0 \) is

\[
\vec{F} = \frac{1}{4\pi \varepsilon_0} \frac{qq_0}{r^2} \hat{r}.
\]  

(22-2)

The direction of \( \vec{F} \) is directly away from the point charge if \( q \) is positive, and directly toward the point charge if \( q \) is negative. The electric field vector is, from Eq. 22-1,

\[
\vec{E} = \frac{\vec{F}}{q_0} = \frac{1}{4\pi \varepsilon_0} \frac{q}{r^2} \hat{r} \quad \text{(point charge)}
\]  

(22-3)

The direction of \( \vec{E} \) is the same as that of the force on the positive test charge: directly away from the point charge if \( q \) is positive, and toward it if \( q \) is negative.

Because there is nothing special about the point we chose for \( q_0 \), Eq. 22-3 gives the field at every point around the point charge \( q \). The field for a positive point charge is shown in Fig. 22-6 in vector form (not as field lines).
We can quickly find the net, or resultant, electric field due to more than one point charge. If we place a positive test charge $q_0$ near $n$ point charges $q_1, q_2, \ldots, q_n$, then, from Eq. 21-7, the net force $\overrightarrow{F}_0$ from the $n$ point charges acting on the test charge is

$$\overrightarrow{F}_0 = \overrightarrow{F}_{01} + \overrightarrow{F}_{02} + \ldots + \overrightarrow{F}_{0n}.$$ 

Therefore, from Eq. 22-1, the net electric field at the position of the test charge is

$$\overrightarrow{E} = \frac{\overrightarrow{E}_0}{q_0} = \frac{\overrightarrow{E}_{01}}{q_0} + \frac{\overrightarrow{E}_{02}}{q_0} + \ldots + \frac{\overrightarrow{E}_{0n}}{q_0} = \overrightarrow{E}_1 + \overrightarrow{E}_2 + \ldots + \overrightarrow{E}_n.$$  \hspace{1cm} (22-4)

Here $\overrightarrow{E}$ is the electric field that would be set up by point charge $i$ acting alone. Equation 22-4 shows us that the principle of superposition applies to electric fields as well as to electrostatic forces.

**CHECKPOINT 1**

The figure here shows a proton $\pi$ and an electron $e$ on an $x$ axis. What is the direction of the electric field due to the electron at (a) point $S$ and (b) point $R$? What is the direction of the net electric field at (c) point $R$ and (d) point $S$?

![Diagram of proton and electron on an x-axis with points S, e, R, and p labeled.]
Figure 22-7a shows three particles with charges $q_1 = +2Q$, $q_2 = -2Q$, and $q_3 = -4Q$, each a distance $d$ from the origin. What net electric field $\vec{E}$ is produced at the origin?

Find the net field at this empty point.

**Figure 22-7(a)** Three particles with charges $q_1$, $q_2$, and $q_3$ are at the same distance $d$ from the origin. (b) The electric field vectors $\vec{E}_1$, $\vec{E}_2$, and $\vec{E}_3$, at the origin due to the three particles. (c) The electric field vector $\vec{E}_3$ and the vector sum $\vec{E}_1 + \vec{E}_2$ at the origin.

**KEY IDEA**

Charges $q_1$, $q_2$, and $q_3$ produce electric field vectors $\vec{E}_1$, $\vec{E}_2$, and $\vec{E}_3$, respectively, at the origin, and the net electric field is the vector sum $\vec{E} = \vec{E}_1 + \vec{E}_2 + \vec{E}_3$. To find this sum, we first must find the magnitudes and orientations of the three field vectors.

**Magnitudes and directions:**

To find the magnitude of $\vec{E}_1$, which is due to $q_1$, we use Eq. 22-3, substituting $d$ for $r$ and $2Q$ for $q$ and obtaining

$$E_1 = \frac{1}{4\pi \varepsilon_0} \frac{2Q}{d^2}.$$

Similarly, we find the magnitudes of $\vec{E}_2$ and $\vec{E}_3$ to be

$$E_2 = \frac{1}{4\pi \varepsilon_0} \frac{2Q}{d^2} \text{ and } E_3 = \frac{1}{4\pi \varepsilon_0} \frac{4Q}{d^2}.$$
We next must find the orientations of the three electric field vectors at the origin. Because \( q_1 \) is a positive charge, the field vector it produces points directly away from it, and because \( q_2 \) and \( q_3 \) are both negative, the field vectors they produce point directly toward each of them. Thus, the three electric fields produced at the origin by the three charged particles are oriented as in Fig. 22-7b. (Caution: Note that we have placed the tails of the vectors at the point where the fields are to be evaluated; doing so decreases the chance of error. Error becomes very probable if the tails of the field vectors are placed on the particles creating the fields.)

**Adding the fields:** We can now add the fields vectorially just as we added force vectors in Chapter 21. However, here we can use symmetry to simplify the procedure.

From Fig. 22-7b, we see that electric fields \( \vec{E}_1 \) and \( \vec{E}_2 \) have the same direction. Hence, their vector sum has that direction and has the magnitude

\[
E_1 + E_2 = \frac{1}{4\pi \varepsilon_0} \frac{2Q}{d^2} + \frac{1}{4\pi \varepsilon_0} \frac{2Q}{d^2} = \frac{1}{4\pi \varepsilon_0} \frac{4Q}{d^2},
\]

which happens to equal the magnitude of field \( \vec{E}_3 \).

We must now combine two vectors, \( \vec{E}_3 \) and the vector sum \( \vec{E}_1 + \vec{E}_2 \), that have the same magnitude and that are oriented symmetrically about the \( x \) axis, as shown in Fig. 22-7c. From the symmetry of Fig. 22-7c, we realize that the equal \( y \) components of our two vectors cancel (one is upward and the other is downward) and the equal \( x \) components add (both are rightward). Thus, the net electric field \( \vec{E} \) at the origin is in the positive direction of the \( x \) axis and has the magnitude

\[
E = 2E_{3x} = 2E_3 \cos 30^\circ = (2) \frac{1}{4\pi \varepsilon_0} \frac{4Q}{d^2} (0.866) = \frac{6.93Q}{4\pi \varepsilon_0 d^2}.
\]

(Answer)

---

**22-5 The Electric Field Due to an Electric Dipole**

Figure 22-8a shows two charged particles of magnitude \( q \) but of opposite sign, separated by a distance \( d \). As was noted in connection with Fig. 22-5, we call this configuration an electric dipole. Let us find the electric field due to the dipole of Fig. 22-8a at a point \( P \), a distance \( z \) from the midpoint of the dipole and on the axis through the particles, which is called the dipole axis.
Figure 22-8

(a) An electric dipole. The electric field vectors $\vec{E}(+)\text{ and }\vec{E}(-)$ at point $P$ on the dipole axis result from the dipole's two charges. Point $P$ is at distances $r(+)\text{ and }r(-)$ from the individual charges that make up the dipole. (b) The dipole moment $\vec{p}$ of the dipole points from the negative charge to the positive charge.

From symmetry, the electric field $\vec{E}$ at point $P$—and also the fields $\vec{E}(+)\text{ and }\vec{E}(-)$ due to the separate charges that make up the dipole—must lie along the dipole axis, which we have taken to be a $z$ axis. Applying the superposition principle for electric fields, we find that the magnitude $E$ of the electric field at $P$ is

$$E = \frac{1}{4\pi \varepsilon_0} \frac{q}{r(+)^2} - \frac{1}{4\pi \varepsilon_0} \frac{q}{r(-)^2}$$

After a little algebra, we can rewrite this equation as

$$E = \frac{q}{4\pi \varepsilon_0 \left(z - \frac{1}{2}d\right)^2} - \frac{q}{4\pi \varepsilon_0 \left(z + \frac{1}{2}d\right)^2}.$$
After forming a common denominator and multiplying its terms, we come to

\[
E = \frac{q}{4\pi \varepsilon_0 z^2} \left( \frac{1}{1 - \left(\frac{d}{2z}\right)^2} - \frac{1}{1 + \left(\frac{d}{2z}\right)^2} \right). \tag{22-6}
\]

We are usually interested in the electrical effect of a dipole only at distances that are large compared with the dimensions of the dipole—that is, at distances such that \(z \gg d\). At such large distances, we have \(d/2z \ll 1\) in Eq. 22-7. Thus, in our approximation, we can neglect the \(d/2z\) term in the denominator, which leaves us with

\[
E = \frac{q d}{2\pi \varepsilon_0 z^3}. \tag{22-8}
\]

The product \(qd\), which involves the two intrinsic properties \(q\) and \(d\) of the dipole, is the magnitude \(p\) of a vector quantity known as the electric dipole moment \(\vec{p}\) of the dipole. (The unit of \(\vec{p}\) is the coulomb-meter.) Thus, we can write Eq. 22-8 as

\[
E = \frac{1}{2\pi \varepsilon_0} \frac{p}{z^3}. \tag{22-9}
\]

The direction of \(\vec{p}\) is taken to be from the negative to the positive end of the dipole, as indicated in Fig. 22-8b. We can use the direction of \(\vec{p}\) to specify the orientation of a dipole.

Equation 22-9 shows that, if we measure the electric field of a dipole only at distant points, we can never find \(q\) and \(d\) separately; instead, we can find only their product. The field at distant points would be unchanged if, for example, \(q\) were doubled and \(d\) simultaneously halved. Although Eq. 22-9 holds only for distant points along the dipole axis, it turns out that \(E\) for a dipole varies as \(1/r^3\) for all distant points, regardless of whether they lie on the dipole axis; here \(r\) is the distance between the point in question and the dipole center.

Inspection of Fig. 22-8 and of the field lines in Fig. 22-5 shows that the direction of \(\vec{E}\) for distant points on the dipole axis is always the direction of the dipole moment vector \(\vec{p}\). This is true whether point \(P\) in Fig. 22-8a is on the upper or the lower part of the dipole axis.

Inspection of Eq. 22-9 shows that if you double the distance of a point from a dipole, the electric field at the point drops by a factor of 8. If you double the distance from a single point charge, however (see Eq. 22-3), the electric field drops only by a factor of 4. Thus the electric field of a dipole decreases more rapidly with distance than does the electric field of a single charge. The physical reason for this rapid decrease in electric field for a dipole is that from distant points a dipole looks like two equal but opposite charges that almost—but not quite—coincide. Thus, their electric fields at distant points almost—but not quite—cancel each other.
**Electric dipole and atmospheric sprites**

Sprites (Fig. 22-9a) are huge flashes that occur far above a large thunderstorm. They were seen for decades by pilots flying at night, but they were so brief and dim that most pilots figured they were just illusions. Then in the 1990s sprites were captured on video. They are still not well understood but are believed to be produced when especially powerful lightning occurs between the ground and storm clouds, particularly when the lightning transfers a huge amount of negative charge \(-q\) from the ground to the base of the clouds (Fig. 22-9b).

![Sprite Image](image)

**Figure 22-9**
(a) Photograph of a sprite. (Courtesy NASA)
(b) Lightning in which a large amount of negative charge is transferred from ground to cloud base.
(c) The cloud–ground system modeled as a vertical electric dipole.

Just after such a transfer, the ground has a complicated distribution of positive charge. However, we can model the electric field due to the charges in the clouds and the ground by assuming a vertical electric dipole that has charge \(-q\) at cloud height \(h\) and charge \(+q\) at below-ground depth \(h\) (Fig. 22-9c). If \(q = 200\, \text{C}\) and \(h = 6.0\, \text{km}\), what is the magnitude of the dipole's electric field at altitude \(z_1 = 30\, \text{km}\) somewhat above the clouds and altitude \(z_2 = 60\, \text{km}\) somewhat above the stratosphere?
**KEY IDEA**

We can approximate the magnitude $E$ of an electric dipole's electric field on the dipole axis with Eq. 22-8.

**Calculations:**

We write that equation as

$$E = \frac{1}{2\pi \varepsilon_0} \frac{q(2h)}{z^3},$$

where $2h$ is the separation between $-q$ and $+q$ in Fig. 22-9c. For the electric field at altitude $z_1 = 30$ km, we find

$$E = \frac{1}{2\pi \varepsilon_0} \frac{(200 \text{ C})(2) \left(6.0 \times 10^3 \text{ m}\right)}{\left(30 \times 10^3 \text{ m}\right)^3} \quad \text{(Answer)}$$

$$= 1.6 \times 10^3 \text{ N/C}.$$  

Similarly, for altitude $z_2 = 60$ km, we find

$$E = 2.0 \times 10^2 \text{ N/C}. \quad \text{(Answer)}$$

As we discuss in Concept Module 22-6, when the magnitude of an electric field exceeds a certain critical value $E_c$, the field can pull electrons out of atoms (ionize the atoms), and then the freed electrons can run into other atoms, causing those atoms to emit light. The value of $E_c$ depends on the density of the air in which the electric field exists. At altitude $z_2 = 60$ km the density of the air is so low that $E = 2.0 \times 10^2 \text{ N/C}$ exceeds $E_c$, and thus light is emitted by the atoms in the air. That light forms sprites. Lower down, just above the clouds at $z_1 = 30$ km, the density of the air is much higher, $E = 1.6 \times 10^3 \text{ N/C}$ does not exceed $E_c$, and no light is emitted. Hence, sprites occur only far above storm clouds.

---

22-6 \hspace{1cm} **The Electric Field Due to a Line of Charge**

We now consider charge distributions that consist of a great many closely spaced point charges (perhaps billions) that are spread along a line, over a surface, or within a volume. Such distributions are said to be **continuous** rather than discrete. Since these distributions can include an enormous number of point charges, we find the electric fields that they produce by means of calculus rather than by considering the point charges one by one. In this section we discuss the electric field caused by a line of charge. We consider a charged surface in the next section. In the next chapter, we shall find the field inside a uniformly charged sphere.
When we deal with continuous charge distributions, it is most convenient to express the charge on an object as a charge density rather than as a total charge. For a line of charge, for example, we would report the linear charge density (or charge per unit length) \( \lambda \), whose SI unit is the coulomb per meter. Table 22-2 shows the other charge densities we shall be using.

Figure 22-10 shows a thin ring of radius \( R \) with a uniform positive linear charge density \( \lambda \) around its circumference. We may imagine the ring to be made of plastic or some other insulator, so that the charges can be regarded as fixed in place. What is the electric field \( \vec{E} \) at point \( P \), a distance \( z \) from the plane of the ring along its central axis?

To answer, we cannot just apply Eq. 22-3, which gives the electric field set up by a point charge, because the ring is obviously not a point charge. However, we can mentally divide the ring into differential elements of charge that are so small that they are like point charges, and then we can apply Eq. 22-3 to each of them. Next, we can add the electric fields set up at \( P \) by all the differential elements. The vector sum of the fields gives us the field set up at \( P \) by the ring.
Let $ds$ be the (arc) length of any differential element of the ring. Since $\lambda$ is the charge per unit (arc) length, the element has a charge of magnitude

$$dg = \lambda \; ds.$$  \hspace{1cm} (22-10)

This differential charge sets up a differential electric field $d\vec{E}$ at point $P$, which is a distance $r$ from the element. Treating the element as a point charge and using Eq. 22-10, we can rewrite Eq. 22-3 to express the magnitude of $d\vec{E}$ as

$$dE = \frac{1}{4\pi \varepsilon_0} \frac{dg}{r^2} = \frac{1}{4\pi \varepsilon_0} \frac{\lambda \; ds}{r^2}. \hspace{1cm} (22-11)$$

From Fig. 22-10, we can rewrite Eq. 22-11 as

$$dE = \frac{1}{4\pi \varepsilon_0} \frac{\lambda \; ds}{\left(z^2 + R^2 \right)^{1/2}}. \hspace{1cm} (22-12)$$

Figure 22-10 shows that $d\vec{E}$ is at angle $\theta$ to the central axis (which we have taken to be a $z$ axis) and has components perpendicular to and parallel to that axis.

Every charge element in the ring sets up a differential field $d\vec{E}$ at $P$, with magnitude given by Eq. 22-12. All the $d\vec{E}$ vectors have identical components parallel to the central axis, in both magnitude and direction. All these $d\vec{E}$ vectors have components perpendicular to the central axis as well; these perpendicular components are identical in magnitude but point in different directions. In fact, for any perpendicular component that points in a given direction, there is another one that points in the opposite direction. The sum of this pair of components, like the sum of all other pairs of oppositely directed components, is zero.

Thus, the perpendicular components cancel and we need not consider them further. This leaves the parallel components; they all have the same direction, so the net electric field at $P$ is their sum.

The parallel component of $d\vec{E}$ shown in Fig. 22-10 has magnitude $dE \cos \theta$. The figure also shows us that

$$\cos \theta = \frac{z}{r} = \frac{z}{\left(z^2 + R^2 \right)^{1/2}}. \hspace{1cm} (22-13)$$

Then multiplying Eq. 22-12 by Eq. 22-13 gives us, for the parallel component of $d\vec{E}$,

$$dE \cos \theta = \frac{z \lambda}{4\pi \varepsilon_0 \left(z^2 + R^2 \right)^{3/2}} ds. \hspace{1cm} (22-14)$$

To add the parallel components $dE \cos \theta$ produced by all the elements, we integrate Eq. 22-14 around the circumference of the ring, from $s = 0$ to $s = 2\pi R$. Since the only quantity in Eq. 22-14 that varies during the integration is $s$, the other quantities can be moved outside the integral sign. The integration then gives us
\[ E = \int dE \cos \theta = \frac{z \lambda}{4\pi \epsilon_0 (z^2 + R^2)^{3/2}} \int_0^{2\pi R} ds \]

\[ = \frac{z \lambda (2\pi R)}{4\pi \epsilon_0 (z^2 + R^2)^{3/2}}. \] (22-15)

Since \( \lambda \) is the charge per length of the ring, the term \( \lambda (2\pi R) \) in Eq. 22-15 is \( q \), the total charge on the ring. We then can rewrite Eq. 22-15 as

\[ E = \frac{qz}{4\pi \epsilon_0 (z^2 + R^2)^{3/2}} \] (charged ring) (22-16)

If the charge on the ring is negative, instead of positive as we have assumed, the magnitude of the field at \( P \) is still given by Eq. 22-16. However, the electric field vector then points toward the ring instead of away from it.

Let us check Eq. 22-16 for a point on the central axis that is so far away that \( z \gg R \). For such a point, the expression \( z^2 + R^2 \) in Eq. 22-16 can be approximated as \( z^2 \), and Eq. 22-16 becomes

\[ E = \frac{1}{4\pi \epsilon_0} \frac{q}{z^2} \] (charged ring at large distance). (22-17)

This is a reasonable result because from a large distance, the ring “looks like” a point charge. If we replace \( z \) with \( r \) in Eq. 22-17, we indeed do have Eq. 22-3, the magnitude of the electric field due to a point charge.

Let us next check Eq. 22-16 for a point at the center of the ring—that is, for \( z = 0 \). At that point, Eq. 22-16 tells us that \( E = 0 \). This is a reasonable result because if we were to place a test charge at the center of the ring, there would be no net electrostatic force acting on it; the force due to any element of the ring would be canceled by the force due to the element on the opposite side of the ring. By Eq. 22-1, if the force at the center of the ring were zero, the electric field there would also have to be zero.

**Electric field of a charged circular rod**

Figure 22-11 shows a plastic rod having a uniformly distributed charge \(-Q\). The rod has been bent in a 120° circular arc of radius \( r \). We place coordinate axes such that the axis of symmetry of the rod lies along the \( x \) axis and the origin is at the center of curvature \( P \) of the rod. In terms of \( Q \) and \( r \), what is the electric field \( \vec{E} \) due to the rod at point \( P \)?
This negatively charged rod is obviously not a particle.  

But we can treat this element as a particle.

These Our jo compo 

---

Here is the field created by the symmetric element, same size and angle.  

We use this to relate the element’s arc length to the angle that it subtends.
Figure 22-11 (a) A plastic rod of charge $-Q$ is a circular section of radius $r$ and central angle $120^\circ$; point $P$ is the center of curvature of the rod. (b)–(c) A differential element in the top half of the rod, at an angle $\theta$ to the $x$ axis and of arc length $ds$, sets up a differential electric field $\vec{dE}$ at $P$. (d) An element $ds'$, symmetric to $ds$ about the $x$ axis, sets up a field $\vec{dE}'$ at $P$ with the same magnitude. (e)–(f) The field components. (g) Arc length $ds$ makes an angle $d\theta$ about point $P$.

**KEY IDEA**

Because the rod has a continuous charge distribution, we must find an expression for the electric fields due to differential elements of the rod and then sum those fields via calculus.

**An element:**

Consider a differential element having arc length $ds$ and located at an angle $\theta$ above the $x$ axis (Figs. 22-11b and c). If we let $\lambda$ represent the linear charge density of the rod, our element $ds$ has a differential charge of magnitude

$$dq = \lambda \ ds.$$

(22-18)

**The element's field:** Our element produces a differential electric field $\vec{dE}$ at point $P$, which is a distance $r$ from the element. Treating the element as a point charge, we can rewrite Eq. 22-3 to express the magnitude of $\vec{dE}$ as

$$dE = \frac{1}{4\pi \varepsilon_0} \frac{dq}{r^2} = \frac{1}{4\pi \varepsilon_0} \frac{\lambda \ ds}{r^2}.$$  

(22-19)

The direction of $\vec{dE}$ is toward $ds$ because charge $dq$ is negative.

**Symmetric partner:** Our element has a symmetrically located (mirror image) element $ds'$ in the bottom half of the rod. The electric field $\vec{dE}'$ set up at $P$ by $ds'$ also has the magnitude given by Eq. 22-19, but the field vector points toward $ds'$ as shown in Fig. 22-11d. If we resolve the electric field vectors of $ds$ and $ds'$ into $x$ and $y$ components as shown in Figs. 22-11e and f, we see that their $y$ components cancel (because they have equal magnitudes and are in opposite directions). We also see that their $x$ components have equal magnitudes and are in the same direction.

**Summing:** Thus, to find the electric field set up by the rod, we need sum (via integration) only the $x$ components of the differential electric fields set up by all the differential elements of the rod. From Fig. 22-11f and Eq. 22-19, we can write the component $dE_x$ set up by $ds$ as

$$dE_x = dE \cos \theta = \frac{1}{4\pi \varepsilon_0} \frac{\lambda}{r^2} \cos \theta \ ds.$$  

(22-20)

Equation 22-20 has two variables, $\theta$ and $s$. Before we can integrate it, we must eliminate one
variable. We do so by replacing $ds$, using the relation
\[ ds = r \, d\theta, \]
in which $d\theta$ is the angle at $P$ that includes arc length $ds$ (Fig. 22-11g). With this replacement, we can integrate Eq. 22.20 over the angle made by the rod at $P$, from $\theta = -60^\circ$ to $\theta = 60^\circ$; that will give us the magnitude of the electric field at $P$ due to the rod:

\[
E = \int dE_x = \int_{-60^\circ}^{60^\circ} \frac{1}{4\pi \varepsilon_0} \frac{\lambda}{r^2} \cos \theta \, r \, d\theta
\]
\[
= \frac{\lambda}{4\pi \varepsilon_0 r} \int_{-60^\circ}^{60^\circ} \cos \theta \, d\theta = \frac{\lambda}{4\pi \varepsilon_0 r} \left[ \sin \theta \right]_{-60^\circ}^{60^\circ}
\]
\[
= \frac{\lambda}{4\pi \varepsilon_0 r} \left[ \sin 60^\circ - \sin(-60^\circ) \right]
\]
\[
= \frac{1.73 \lambda}{4\pi \varepsilon_0 r}.
\]

(If we had reversed the limits on the integration, we would have gotten the same result but with a minus sign. Since the integration gives only the magnitude of $\vec{E}$, we would then have discarded the minus sign.)

**Charge density:** To evaluate $\lambda$, we note that the rod subtends an angle of $120^\circ$ and so is one-third of a full circle. Its arc length is then $2\pi r/3$, and its linear charge density must be

\[
\lambda = \frac{\text{charge}}{\text{length}} = \frac{Q}{2\pi r/3} = \frac{0.477Q}{r}.
\]

Substituting this into Eq. 22.21 and simplifying give us

\[
E = \frac{(1.73) (0.477Q)}{4\pi \varepsilon_0 r^2}
\]
\[
= \frac{0.83Q}{4\pi \varepsilon_0 r^2}.
\]

(Answer)

The direction of $\vec{E}$ is toward the rod, along the axis of symmetry of the charge distribution.

We can write $\vec{E}$ in unit-vector notation as

\[
\vec{E} = \frac{0.83Q}{4\pi \varepsilon_0 r^2} \hat{i}.
\]

---

**A Field Guide for Lines of Charge**

Here is a generic guide for finding the electric field $\vec{E}$ produced at a point $P$ by a line of uniform charge, either circular or straight. The general strategy is to pick out an element
dq of the charge, find \( d\vec{E} \) due to that element, and integrate \( d\vec{E} \) over the entire line of charge.

**Step 1.** If the line of charge is circular, let \( ds \) be the arc length of an element of the distribution. If the line is straight, run an \( x \) axis along it and let \( dx \) be the length of an element. Mark the element on a sketch.

**Step 2.** Relate the charge \( dq \) of the element to the length of the element with either \( dq = \lambda \, ds \) or \( dq = \lambda \, dx \). Consider \( dq \) and \( \lambda \) to be positive, even if the charge is actually negative. (The sign of the charge is used in the next step.)

**Step 3.** Express the field \( \vec{dE} \) produced at \( P \) by \( dq \) with Eq. 22-3, replacing \( q \) in that equation with either \( \lambda \, ds \) or \( \lambda \, dx \). If the charge on the line is positive, then at \( P \) draw a vector \( \vec{dE} \) that points directly away from \( dq \). If the charge is negative, draw the vector pointing directly toward \( dq \).

**Step 4.** Always look for any symmetry in the situation. If \( P \) is on an axis of symmetry of the charge distribution, resolve the field \( \vec{dE} \) produced by \( dq \) into components that are perpendicular and parallel to the axis of symmetry. Then consider a second element \( dq' \) that is located symmetrically to \( dq \) about the line of symmetry. At \( P \) draw the vector \( \vec{dE'} \) that this symmetrical element produces and resolve it into components. One of the components produced by \( dq \) is a canceling component; it is canceled by the corresponding component produced by \( dq' \) and needs no further attention. The other component produced by \( dq \) is an adding component; it adds to the corresponding component produced by \( dq' \). Add the adding components of all the elements via integration.

**Step 5.** Here are four general types of uniform charge distributions, with strategies for the integral of step 4.

*Ring*, with point \( P \) on (central) axis of symmetry, as in Fig. 22-10. In the expression for \( dE \), replace \( r^2 \) with \( z^2 + R^2 \), as in Eq. 22-12. Express the adding component of \( \vec{dE} \) in terms of \( \theta \). That introduces \( \cos \theta \), but \( \theta \) is identical for all elements and thus is not a variable. Replace \( \cos \theta \) as in Eq. 22-13. Integrate over \( s \), around the circumference of the ring.

*Circular arc*, with point \( P \) at the center of curvature, as in Fig. 22-11. Express the adding component of \( \vec{dE} \) in terms of \( \theta \). That introduces either \( \sin \theta \) or \( \cos \theta \). Reduce the resulting two variables \( s \) and \( \theta \) to one, \( \theta \), by replacing \( ds \) with \( r \, d\theta \). Integrate over \( \theta \) from one end of the arc to the other end.

*Straight line*, with point \( P \) on an extension of the line, as in Fig. 22-12a. In the expression for \( dE \), replace \( r \) with \( x \). Integrate over \( x \), from end to end of the line of charge.

*Straight line*, with point \( P \) at perpendicular distance \( y \) from the line of charge, as in Fig. 22-12b. In the expression for \( dE \), replace \( r \) with an expression involving \( x \) and \( y \). If \( P \) is on the perpendicular bisector of the line of charge, find an expression for the adding component of \( \vec{dE} \). That will introduce either \( \sin \theta \) or \( \cos \theta \). Reduce the resulting two variables \( x \) and \( \theta \) to one, \( x \), by replacing the trigonometric function with an expression (its definition) involving \( x \) and \( y \). Integrate over \( x \) from end to end of the line of charge. If \( P \) is not on a line of symmetry, as in Fig. 22-12c, set up an integral to
sum the components \(dE_x\), and integrate over \(x\) to find \(E_x\). Also set up an integral to sum the components \(dE_y\), and integrate over \(x\) again to find \(E_y\). Use the components \(E_x\) and \(E_y\) in the usual way to find the magnitude \(E\) and the orientation of \(\mathbf{E}\).

\[
\begin{align*}
\text{(a)} & \\
\text{(b)} & \\
\text{(c)} & 
\end{align*}
\]

**Figure 22-12**

(a) Point \(P\) is on an extension of the line of charge. (b) \(P\) is on a line of symmetry of the line of charge, at perpendicular distance \(y\) from that line. (c) Same as (b) except that \(P\) is not on a line of symmetry.

**Step 6.** One arrangement of the integration limits gives a positive result. The reverse gives the same result with a minus sign; discard the minus sign. If the result is to be stated in terms of the total charge \(Q\) of the distribution, replace \(\lambda\) with \(Q/L\), in which \(L\) is the length of the distribution.

**CHECKPOINT 2**

The figure here shows three nonconducting rods, one circular and two straight. Each has a uniform charge of magnitude \(Q\) along its top half and another along its bottom half. For each rod, what is the direction of the net electric field at point \(P\)?
The Electric Field Due to a Charged Disk

Figure 22-13 shows a circular plastic disk of radius $R$ that has a positive surface charge of uniform density $\sigma$ on its upper surface (see Table 22-1). What is the electric field at point $P$, a distance $z$ from the disk along its central axis?

Our plan is to divide the disk into concentric flat rings and then to calculate the electric field at point $P$ by adding up (that is, by integrating) the contributions of all the rings. Figure 22-13 shows one such ring, with radius $r$ and radial width $dr$. Since $\sigma$ is the charge per unit area, the charge on the ring is

$$dq = \sigma \, dA = \sigma (2\pi r \, dr),$$

(22-22)

where $dA$ is the differential area of the ring.

We have already solved the problem of the electric field due to a ring of charge. Substituting $dq$ from Eq. 22-22 for $q$ in Eq. 22-16, and replacing $R$ in Eq. 22-16 with $r$, we obtain an expression for the electric field $dE$ at $P$ due to the arbitrarily chosen flat ring of charge shown in Fig. 22-13:

$$dE = \frac{z \sigma (2\pi r \, dr)}{4\pi \varepsilon_0 \left(z^2 + r^2\right)^{3/2}},$$

which we may write as

$$dE = \frac{\sigma z}{4 \varepsilon_0} \frac{2r \, dr}{\left(z^2 + r^2\right)^{3/2}}.$$

(22-23)
We can now find \( E \) by integrating Eq. 22-23 over the surface of the disk—that is, by integrating with respect to the variable \( r \) from \( r = 0 \) to \( r = R \). Note that \( z \) remains constant during this process. We get

\[
E = \int dE = \frac{\sigma z}{4 \varepsilon_0} \int_0^R \left( \frac{z^2 + r^2}{(z^2 + r^2)^{3/2}} \right) (2r) \, dr.
\]

To solve this integral, we cast it in the form \( \int X^m \, dX \) by setting \( X = (z^2 + r^2) \), \( m = -\frac{3}{2} \), and \( dX = (2r) \, dr \). For the recast integral we have

\[
\int X^m \, dX = \frac{X^{m+1}}{m+1},
\]

and so Eq. 22-24 becomes

\[
E = \frac{\sigma z}{4 \varepsilon_0} \left[ \frac{(z^2 + r^2)^{-1/2}}{-\frac{1}{2}} \right]^R_0.
\]

Taking the limits in Eq. 22-25 and rearranging, we find

\[
E = \frac{\sigma}{2 \varepsilon_0} \left( 1 - \frac{z}{\sqrt{z^2 + R^2}} \right) \quad \text{(charged disk)}
\]

as the magnitude of the electric field produced by a flat, circular, charged disk at points on its central axis. (In carrying out the integration, we assumed that \( z \geq 0 \).)

If we let \( R \to \infty \) while keeping \( z \) finite, the second term in the parentheses in Eq. 22-26 approaches zero, and this equation reduces to

\[
E = \frac{\sigma}{2 \varepsilon_0} \quad \text{(infinite sheet)}.
\]

This is the electric field produced by an infinite sheet of uniform charge located on one side of a nonconductor such as plastic. The electric field lines for such a situation are shown in Fig. 22-3.

We also get Eq. 22-27 if we let \( z \to 0 \) in Eq. 22-26 while keeping \( R \) finite. This shows that at points very close to the disk, the electric field set up by the disk is the same as if the disk were infinite in extent.

---

**CHECKPOINT 3**

(a) In the figure, what is the direction of the electrostatic force on the electron due to the external electric field shown? (b) In which direction will the electron accelerate if it is moving parallel to the y axis before it encounters the external field? (c) If, instead, the electron is initially moving rightward, will its speed increase, decrease, or remain constant?
In the preceding four sections we worked at the first of our two tasks: given a charge distribution, to find the electric field it produces in the surrounding space. Here we begin the second task: to determine what happens to a charged particle when it is in an electric field set up by other stationary or slowly moving charges.

What happens is that an electrostatic force acts on the particle, as given by

\[ \vec{F} = q\vec{E}, \]  

in which \( q \) is the charge of the particle (including its sign) and \( \vec{E} \) is the electric field that other charges have produced at the location of the particle. (The field is not the field set up by the particle itself; to distinguish the two fields, the field acting on the particle in Eq. \( 22-28 \) is often called the external field. A charged particle or object is not affected by its own electric field.) Equation \( 22-28 \) tells us

- The electrostatic force \( \vec{F} \) acting on a charged particle located in an external electric field \( \vec{E} \) has the direction of \( \vec{E} \) if the charge \( q \) of the particle is positive and has the opposite direction if \( q \) is negative.

**Measuring the Elementary Charge**

Equation \( 22-28 \) played a role in the measurement of the elementary charge \( e \) by American physicist Robert A. Millikan in 1910–1913. Figure \( 22-14 \) is a representation of his apparatus. When tiny oil drops are sprayed into chamber A, some of them become charged, either positively or negatively, in the process. Consider a drop that drifts downward through the small hole in plate \( P_1 \) and into chamber C. Let us assume that this drop has a negative charge \( q \).
Figure 22-14 The Millikan oil-drop apparatus for measuring the elementary charge \( e \). When a charged oil drop drifted into chamber C through the hole in plate \( P_1 \), its motion could be controlled by closing and opening switch S and thereby setting up or eliminating an electric field in chamber C. The microscope was used to view the drop, to permit timing of its motion.

If switch S in Fig. 22-14 is open as shown, battery B has no electrical effect on chamber C. If the switch is closed (the connection between chamber C and the positive terminal of the battery is then complete), the battery causes an excess positive charge on conducting plate \( P_1 \) and an excess negative charge on conducting plate \( P_2 \). The charged plates set up a downward-directed electric field \( \vec{E} \) in chamber C. According to Eq. 22-28, this field exerts an electrostatic force on any charged drop that happens to be in the chamber and affects its motion. In particular, our negatively charged drop will tend to drift upward.

By timing the motion of oil drops with the switch opened and with it closed and thus determining the effect of the charge \( q \), Millikan discovered that the values of \( q \) were always given by

\[
q = ne, \quad \text{for } n = 0, \pm 1, \pm 2, \pm 3, \ldots
\]

in which \( e \) turned out to be the fundamental constant we call the elementary charge, \( 1.60 \times 10^{-19} \) C. Millikan’s experiment is convincing proof that charge is quantized, and he earned the 1923 Nobel Prize in physics in part for this work. Modern measurements of the elementary charge rely on a variety of interlocking experiments, all more precise than the pioneering experiment of Millikan.

Ink-Jet Printing

The need for high-quality, high-speed printing has caused a search for an alternative to impact printing, such as occurs in a standard typewriter. Building up letters by squirting tiny drops of ink at the paper is one such alternative.

Figure 22-15 shows a negatively charged drop moving between two conducting deflecting plates, between which a uniform, downward-directed electric field \( \vec{E} \) has been set up. The drop is deflected upward according to Eq. 22-28 and then strikes the paper at a position that is determined by the magnitudes of \( \vec{E} \) and the charge \( q \) of the drop.
Ink-jet printer. Drops shot from generator $G$ receive a charge in charging unit $C$. An input signal from a computer controls the charge and thus the effect of field $\vec{E}$ on where the drop lands on the paper.

In practice, $E$ is held constant and the position of the drop is determined by the charge $q$ delivered to the drop in the charging unit, through which the drop must pass before entering the deflecting system. The charging unit, in turn, is activated by electronic signals that encode the material to be printed.

**Electrical Breakdown and Sparking**

If the magnitude of an electric field in air exceeds a certain critical value $E_c$, the air undergoes *electrical breakdown*, a process whereby the field removes electrons from the atoms in the air. The air then begins to conduct electric current because the freed electrons are propelled into motion by the field. As they move, they collide with any atoms in their path, causing those atoms to emit light. We can see the paths, commonly called sparks, taken by the freed electrons because of that emitted light. Figure 22-16 shows sparks above charged metal wires where the electric fields due to the wires cause electrical breakdown of the air.
Motion of a charged particle in an electric field

Figure 22-17 shows the deflecting plates of an ink-jet printer, with superimposed coordinate axes. An ink drop with a mass \( m \) of \( 1.3 \times 10^{-10} \) kg and a negative charge of magnitude \( Q = 1.5 \times 10^{-13} \) C enters the region between the plates, initially moving along the \( x \) axis with speed \( v_x = 18 \) m/s. The length \( L \) of each plate is 1.6 cm. The plates are charged and thus produce an electric field at all points between them. Assume that field \( \vec{E} \) is downward directed, is uniform, and has a magnitude of \( 1.4 \times 10^6 \) N/C. What is the vertical deflection of the drop at the far edge of the plates? (The gravitational force on the drop is small relative to the electrostatic force acting on the drop and can be neglected.)

**Figure 22-17** An ink drop of mass \( m \) and charge magnitude \( Q \) is deflected in the electric field of an ink-jet printer.

**KEY IDEA**

The drop is negatively charged and the electric field is directed downward. From Eq. 22-28, a constant electrostatic force of magnitude \( QE \) acts upward on the charged drop. Thus, as the drop travels parallel to the \( x \) axis at constant speed \( v_x \), it accelerates upward with some constant acceleration \( a_y \).

**Calculations:**

Applying Newton’s second law \( (F = ma) \) for components along the \( y \) axis, we find that

\[
  a_y = \frac{F}{m} = \frac{QE}{m}. \tag{22-30}
\]

Let \( t \) represent the time required for the drop to pass through the region between the plates. During \( t \) the vertical and horizontal displacements of the drop are

\[
  y = \frac{1}{2} a_y t^2 \quad \text{and} \quad L = v_x t, \tag{22-31}
\]

respectively. Eliminating \( t \) between these two equations and substituting Eq. 22-30 for \( a_y \),
A Dipole in an Electric Field

We have defined the electric dipole moment \( \vec{P} \) of an electric dipole to be a vector that points from the negative to the positive end of the dipole. As you will see, the behavior of a dipole in a uniform external electric field \( \vec{E} \) can be described completely in terms of the two vectors \( \vec{E} \) and \( \vec{P} \), with no need of any details about the dipole's structure.

A molecule of water (H\(_2\)O) is an electric dipole; Fig. 22-18 shows why. There the black dots represent the oxygen nucleus (having eight protons) and the two hydrogen nuclei (having one proton each). The colored enclosed areas represent the regions in which electrons can be located around the nuclei.

\[
\mathbf{y} = \frac{Q \epsilon \ell^2}{2m v_x^2} = \frac{(1.5 \times 10^{-13} \text{C}) (1.4 \times 10^6 \text{N/C}) (1.6 \times 10^{-2} \text{m})^2}{(2)(1.3 \times 10^{-10} \text{Kg})(18 \text{ m/s})^2} = 6.4 \times 10^{-4} \text{m} = 0.64 \text{ mm}
\]

In a water molecule, the two hydrogen atoms and the oxygen atom do not lie on a straight line but form an angle of about 105°, as shown in Fig. 22-18. As a result, the molecule has a definite “oxygen side” and “hydrogen side.” Moreover, the 10 electrons of the molecule tend to remain closer to the
oxygen nucleus than to the hydrogen nuclei. This makes the oxygen side of the molecule slightly more negative than the hydrogen side and creates an electric dipole moment \( \vec{P} \) that points along the symmetry axis of the molecule as shown. If the water molecule is placed in an external electric field, it behaves as would be expected of the more abstract electric dipole of Fig. 22-8.

To examine this behavior, we now consider such an abstract dipole in a uniform external electric field \( \vec{E} \), as shown in Fig. 22-19a. We assume that the dipole is a rigid structure that consists of two centers of opposite charge, each of magnitude \( q \), separated by a distance \( d \). The dipole moment \( \vec{P} \) makes an angle \( \theta \) with field \( \vec{E} \).

![Figure 22-19](https://example.com/fig22-19.png)

**(a)** An electric dipole in a uniform external electric field \( \vec{E} \). Two centers of equal but opposite charge are separated by distance \( d \). The line between them represents their rigid connection. **(b)** Field \( \vec{E} \) causes a torque \( \vec{\tau} \) on the dipole. The direction of \( \vec{\tau} \) is into the page, as represented by the symbol \( \bigotimes \).

Electrostatic forces act on the charged ends of the dipole. Because the electric field is uniform, those forces act in opposite directions (as shown in Fig. 22-19a) and with the same magnitude \( F = qE \). Thus, because the field is uniform, the net force on the dipole from the field is zero and the center of mass of the dipole does not move. However, the forces on the charged ends do produce a net torque \( \vec{\tau} \) on the dipole about its center of mass. The center of mass lies on the line connecting the charged ends, at some distance \( x \) from one end and thus a distance \( d - x \) from the other end. From Eq. 10-39 \( (\tau = rF \sin \theta) \), we can write the magnitude of the net torque \( \vec{\tau} \) as

\[
\tau = Fx \sin \theta + F(d - x) \sin \theta = Fd \sin \theta. \tag{22-32}
\]

We can also write the magnitude of \( \vec{\tau} \) in terms of the magnitudes of the electric field \( E \) and the dipole moment \( p = qd \). To do so, we substitute \( qE \) for \( F \) and \( p/q \) for \( d \) in Eq. 22-32, finding that the magnitude of \( \vec{\tau} \) is

\[
\tau = pE \sin \theta. \tag{22-33}
\]
We can generalize this equation to vector form as

\[ \vec{\tau} = \vec{p} \times \vec{E} \quad \text{(torque on a dipole).} \]  

(22-34)

Vectors \( \vec{P} \) and \( \vec{E} \) are shown in Fig. 22-19b. The torque acting on a dipole tends to rotate \( \vec{P} \) (hence the dipole) into the direction of field \( \vec{E} \), thereby reducing \( \theta \). In Fig. 22-19, such rotation is clockwise. As we discussed in Chapter 10, we can represent a torque that gives rise to a clockwise rotation by including a minus sign with the magnitude of the torque. With that notation, the torque of Fig. 22-19 is

\[ \tau = -pE \sin \theta. \]  

(22-35)

### Potential Energy of an Electric Dipole

Potential energy can be associated with the orientation of an electric dipole in an electric field. The dipole has its least potential energy when it is in its equilibrium orientation, which is when its moment \( \vec{P} \) is lined up with the field \( \vec{E} \) (then \( \tau = \vec{P} \times \vec{E} = 0 \)). It has greater potential energy in all other orientations. Thus the dipole is like a pendulum, which has its least gravitational potential energy in its equilibrium orientation—at its lowest point. To rotate the dipole or the pendulum to any other orientation requires work by some external agent.

In any situation involving potential energy, we are free to define the zero-potential-energy configuration in a perfectly arbitrary way because only differences in potential energy have physical meaning. It turns out that the expression for the potential energy of an electric dipole in an external electric field is simplest if we choose the potential energy to be zero when the angle \( \theta \) in Fig. 22-19 is 90°. We then can find the potential energy \( U \) of the dipole at any other value of \( \theta \) with Eq. 8-1 \( (\Delta U = -W) \) by calculating the work \( W \) done by the field on the dipole when the dipole is rotated to that value of \( \theta \) from 90°. With the aid of Eq. 10-53 \( (W = \int \tau \, d\theta) \) and Eq. 22-35, we find that the potential energy \( U \) at any angle \( \theta \) is

\[ U = -W = - \int_{90^\circ}^{\theta} \tau \, d\theta = \int_{90^\circ}^{\theta} pE \sin \theta \, d\theta. \]  

(22-36)

Evaluating the integral leads to

\[ U = -pE \cos \theta. \]  

(22-37)

We can generalize this equation to vector form as

\[ U = -\vec{P} \cdot \vec{E} \quad \text{(potential energy of a dipole).} \]  

(22-38)

Equations 22-37 and 22-38 show us that the potential energy of the dipole is least \( (U = -pE) \) when \( \theta = 0 \) (\( \vec{P} \) and \( \vec{E} \) are in the same direction); the potential energy is greatest \( (U = pE) \) when \( \theta = 180^\circ \) (\( \vec{P} \) and \( \vec{E} \) are in opposite directions).

When a dipole rotates from an initial orientation \( \theta_i \) to another orientation \( \theta_f \), the work \( W \) done on the dipole by the electric field is

\[ W = -\Delta U = -(U_f - U_i), \]  

(22-39)

where \( U_f \) and \( U_i \) are calculated with Eq. 22-38. If the change in orientation is caused by an applied torque (commonly said to be due to an external agent), then the work \( W_a \) done on the dipole by the applied torque is the negative of the work done on the dipole by the field; that is,
The figure shows four orientations of an electric dipole in an external electric field. Rank the orientations according to (a) the magnitude of the torque on the dipole and (b) the potential energy of the dipole, greatest first.

(1) +

(2) +

(3) +

(4) +

\[ W_a = -W = (U_f - U_i). \]  

Microwave Cooking

Food can be warmed and cooked in a microwave oven if the food contains water because water molecules are electric dipoles. When you turn on the oven, the microwave source sets up a rapidly oscillating electric field \( \vec{E} \) within the oven and thus also within the food. From Eq. 22-34, we see that any electric field \( \vec{E} \) produces a torque on an electric dipole moment \( \vec{P} \) to align \( \vec{P} \) with \( \vec{E} \). Because the oven’s \( \vec{E} \) oscillates, the water molecules continuously flip-flop in a frustrated attempt to align with \( \vec{E} \).

Energy is transferred from the electric field to the thermal energy of the water (and thus of the food) where three water molecules happened to have bonded together to form a group. The flip-flop breaks some of the bonds. When the molecules reform the bonds, energy is transferred to the random motion of the group and then to the surrounding molecules. Soon, the thermal energy of the water is enough to cook the food. Sometimes the heating is surprising. If you heat a jelly donut, for example, the jelly (which holds a lot of water) heats far more than the donut material (which holds much less water). Although the exterior of the donut may not be hot, biting into the jelly can burn you. If water molecules were not electric dipoles, we would not have microwave ovens.

Torque and energy of an electric dipole in an electric field

A neutral water molecule (H\(_2\)O) in its vapor state has an electric dipole moment of magnitude
6.2 \times 10^{-30} \text{ C} \cdot \text{m}.

(a) How far apart are the molecule's centers of positive and negative charge?

**KEY IDEA**

A molecule's dipole moment depends on the magnitude \( q \) of the molecule's positive or negative charge and the charge separation \( d \).

**Calculation:**

There are 10 electrons and 10 protons in a neutral water molecule; so the magnitude of its dipole moment is

\[ p = qd = (10e) \langle d \rangle, \]

in which \( d \) is the separation we are seeking and \( e \) is the elementary charge. Thus,

\[
d = \frac{p}{10e} = \frac{6.2 \times 10^{-30} \text{ C} \cdot \text{m}}{(10) \langle 1.60 \times 10^{-19} \text{ C} \rangle}
\]

\[
= 3.9 \times 10^{-12} \text{ m} = 3.9 \text{ pm}
\]

This distance is not only small, but it is also actually smaller than the radius of a hydrogen atom.

(b) If the molecule is placed in an electric field of 1.5 \times 10^4 \text{ N/C}, what maximum torque can the field exert on it? (Such a field can easily be set up in the laboratory.)

**KEY IDEA**

The torque on a dipole is maximum when the angle \( \theta \) between \( \vec{P} \) and \( \vec{E} \) is 90°.

**Calculation:**

Substituting \( \theta = 90^\circ \) in Eq. 22-33 yields

\[
\tau = pE \sin \theta
\]

\[
= \left( 6.2 \times 10^{-30} \text{ C} \cdot \text{m} \right) \langle 1.5 \times 10^4 \text{ N/C} \rangle \langle \sin 90^\circ \rangle
\]

\[
= 9.3 \times 10^{-26} \text{ N} \cdot \text{m}
\]

(c) How much work must an external agent do to rotate this molecule by 180° in this field, starting from its fully aligned position, for which \( \theta = 0^\circ \)?

**KEY IDEA**

The work done by an external agent (by means of a torque applied to the molecule) is equal to the change in the molecule's potential energy due to the change in orientation.

**Calculations:**
From Eq. 22-40, we find

\[
W_{\alpha} = \frac{U_{180^\circ} - U_0}{2} = \left( -pE \cos 180^\circ \right) - \left( -pE \cos 0 \right)
\]

\[
= 2pE = (2) \left( 6.2 \times 10^{-30} C \cdot m \right) \left( 1.5 \times 10^4 N / C \right)
\]

\[
= 1.9 \times 10^{-25} J
\]

---

**Electric Field** To explain the electrostatic force between two charges, we assume that each charge sets up an electric field in the space around it. The force acting on each charge is then due to the electric field set up at its location by the other charge.

**Definition of Electric Field** The electric field \( \vec{E} \) at any point is defined in terms of the electrostatic force \( \vec{F} \) that would be exerted on a positive test charge \( q_0 \) placed there:

\[
\vec{E} = \frac{\vec{F}}{q_0}
\]  

**Electric Field Lines** Electric field lines provide a means for visualizing the direction and magnitude of electric fields. The electric field vector at any point is tangent to a field line through that point. The density of field lines in any region is proportional to the magnitude of the electric field in that region. Field lines originate on positive charges and terminate on negative charges.

**Field Due to a Point Charge** The magnitude of the electric field \( \vec{E} \) set up by a point charge \( q \) at a distance \( r \) from the charge is

\[
\vec{E} = \frac{1}{4\pi \varepsilon_0} \frac{q}{r^2} \hat{r}
\]  

The direction of \( \vec{E} \) is away from the point charge if the charge is positive and toward it if the charge is negative.

**Field Due to an Electric Dipole** An electric dipole consists of two particles with charges of equal magnitude \( q \) but opposite sign, separated by a small distance \( d \). Their electric dipole moment
\( \vec{P} \) has magnitude \( qd \) and points from the negative charge to the positive charge. The magnitude of the electric field set up by the dipole at a distant point on the dipole axis (which runs through both charges) is

\[
E = \frac{1}{2\pi \varepsilon_0} \frac{P}{z^3},
\]

where \( z \) is the distance between the point and the center of the dipole.

**Field Due to a Continuous Charge Distribution** The electric field due to a continuous charge distribution is found by treating charge elements as point charges and then summing, via integration, the electric field vectors produced by all the charge elements to find the net vector.

**Force on a Point Charge in an Electric Field** When a point charge \( q \) is placed in an external electric field \( \vec{E} \), the electrostatic force \( \vec{F} \) that acts on the point charge is

\[
\vec{F} = q \vec{E}.
\]

Force \( \vec{F} \) has the same direction as \( \vec{E} \) if \( q \) is positive and the opposite direction if \( q \) is negative.

**Dipole in an Electric Field** When an electric dipole of dipole moment \( \vec{P} \) is placed in an electric field \( \vec{E} \), the field exerts a torque \( \vec{\tau} \) on the dipole:

\[
\vec{\tau} = \vec{P} \times \vec{E}.
\]

The dipole has a potential energy \( U \) associated with its orientation in the field:

\[
U = -\vec{P} \cdot \vec{E}.
\]

This potential energy is defined to be zero when \( \vec{P} \) is perpendicular to \( \vec{E} \); it is least \( (U = -pE) \) when \( \vec{P} \) is aligned with \( \vec{E} \) and greatest \( (U = pE) \) when \( \vec{P} \) is directed opposite \( \vec{E} \).
Figure 22-20 shows three arrangements of electric field lines. In each arrangement, a proton is released from rest at point A and is then accelerated through point B by the electric field. Points A and B have equal separations in the three arrangements. Rank the arrangements according to the linear momentum of the proton at point B, greatest first.

(a)  
(b)  
(c)  

2 Figure 22-21 shows two square arrays of charged particles. The squares, which are centered on point P, are misaligned. The particles are separated by either d or d/2 along the perimeters of the squares. What are the magnitude and direction of the net electric field at P?

3 In Fig. 22-22, two particles of charge -q are arranged symmetrically about the y axis; each produces an electric field at point P on that axis. (a) Are the magnitudes of the fields at P equal? (b) Is each electric field directed toward or away from the charge producing it? (c) Is the magnitude of the net electric field at P equal to the sum of the magnitudes E of the two field vectors (is it equal to 2E)? (d) Do the x components of those two field vectors add or cancel? (e) Do their y components add or cancel? (f) Is the direction of the net field at P that of the canceling components or the adding components? (g) What is the direction of the net field?
Figure 22-23 shows four situations in which four charged particles are evenly spaced to the left and right of a central point. The charge values are indicated. Rank the situations according to the magnitude of the net electric field at the central point, greatest first.

1. \( +e \quad -e \quad -e \quad +e \)
2. \( +e \quad +e \quad -e \quad -e \)
3. \( -e \quad +e \quad +e \quad +e \)
4. \( -e \quad -e \quad +e \quad -e \)

Figure 22-23 Question 4.

Figure 22-24 shows two charged particles fixed in place on an axis. (a) Where on the axis (other than at an infinite distance) is there a point at which their net electric field is zero: between the charges, to their left, or to their right? (b) Is there a point of zero net electric field anywhere off the axis (other than at an infinite distance)?

\( +q \quad -3q \)

Figure 22-24 Question 5.

In Fig. 22-25, two identical circular nonconducting rings are centered on the same line. For three situations, the uniform charges on rings A and B are, respectively, (1) \( q_0 \) and \( q_0 \), (2) \(-q_0 \) and \(-q_0 \), and (3) \(-q_0 \) and \(-q_0 \). Rank the situations according to the magnitude of the net electric field at (a) point \( P_1 \) midway between the rings, (b) point \( P_2 \) at the center of ring B, and (c) point \( P_3 \) to the right of ring B, greatest first.

\( P_1 \) \quad \( P_2 \) \quad \( P_3 \)

Figure 22-25 Question 6.

The potential energies associated with four orientations of an electric dipole in an electric field are (1) \(-5U_0\), (2) \(-7U_0\), (3) \(3U_0\), and (4) \(5U_0\), where \( U_0 \) is positive. Rank the orientations according to (a) the angle between the electric dipole moment \( \vec{P} \) and the electric field \( \vec{E} \), and (b) the magnitude of the torque on the electric dipole, greatest first.

(a) In the Checkpoint of Section 22-9, if the dipole rotates from orientation 1 to orientation 2, is the work done on the dipole by the field positive, negative, or zero? (b) If, instead, the dipole rotates from orientation 1 to orientation 4, is the work done by the field more than, less than, or the same as in (a)?

Top of Form
Figure 22-26 shows two disks and a flat ring, each with the same uniform charge $Q$. Rank the objects according to the magnitude of the electric field they create at points $P$ (which are at the same vertical heights), greatest first.

In Fig. 22-27, an electron $e$ travels through a small hole in plate $A$ and then toward plate $B$. A uniform electric field in the region between the plates then slows the electron without deflecting it. (a) What is the direction of the field? (b) Four other particles similarly travel through small holes in either plate $A$ or plate $B$ and then into the region between the plates. Three have charges $+q_1$, $+q_2$, and $-q_3$. The fourth (labeled $n$) is a neutron, which is electrically neutral. Does the speed of each of those four other particles increase, decrease, or remain the same in the region between the plates?

In Fig. 22-28a, a circular plastic rod with uniform charge $+Q$ produces an electric field of magnitude $E$ at the center of curvature (at the origin). In Figs. 22-28b, c, and d, more circular rods, each with identical uniform charges $+Q$, are added until the circle is complete. A fifth arrangement (which would be labeled e) is like that in d except the rod in the fourth quadrant has charge $-Q$. Rank the five arrangements according to the magnitude of the electric field at the center of curvature, greatest first.
sec. 22-3 Electric Field Lines

1. Sketch qualitatively the electric field lines both between and outside two concentric conducting spherical shells when a uniform positive charge $q_1$ is on the inner shell and a uniform negative charge $-q_2$ is on the outer. Consider the cases $q_1 > q_2$, $q_1 = q_2$, and $q_1 < q_2$.

2. In Fig. 22-29 the electric field lines on the left have twice the separation of those on the right. (a) If the magnitude of the field at $A$ is 40 N/C, what is the magnitude of the force on a proton at $A$? (b) What is the magnitude of the field at $B$?

sec. 22-4 The Electric Field Due to a Point Charge

3 SSM The nucleus of a plutonium-239 atom contains 94 protons. Assume that the nucleus is a sphere with radius 6.64 fm and with the charge of the protons uniformly spread through the sphere. At the nucleus surface, what are the (a) magnitude and (b) direction (radially inward or outward) of the electric field produced by the protons?

4. Two particles are attached to an $x$ axis: particle 1 of charge $-2.00 \times 10^{-7}$ C at $x = 6.00$ cm, particle 2 of charge $+2.00 \times 10^{-7}$ C at $x = 21.0$ cm. Midway between the particles, what is their net electric
field in unit-vector notation?

5 SSM What is the magnitude of a point charge whose electric field 50 cm away has the magnitude 2.0 N/C?

6 What is the magnitude of a point charge that would create an electric field of 1.00 N/C at points 1.00 m away?

7 SSM WWW ILW In Fig. 22-30, the four particles form a square of edge length \(a = 5.00\) cm and have charges \(q_1 = +10.0\) nC, \(q_2 = -20.0\) nC, \(q_3 = +20.0\) nC, and \(q_4 = -10.0\) nC. In unit-vector notation, what net electric field do the particles produce at the square's center?

8 In Fig. 22-31, the four particles are fixed in place and have charges \(q_1 = q_2 = +5e\), \(q_3 = +3e\), and \(q_4 = -12e\). Distance \(d = 5.0\) μm. What is the magnitude of the net electric field at point \(P\) due to the particles?

9 Figure 22-32 shows two charged particles on an \(x\) axis: 

\(-q = -3.20 \times 10^{-19} \text{ C at } x = -3.00 \text{ m}\) 

\(q = 3.20 \times 10^{-19} \text{ C at } x = +3.00 \text{ m}\). What are the (a) magnitude and (b) direction (relative to the positive direction of the \(x\) axis) of the net electric field produced at point \(P\) at \(y = 4.00 \text{ m}\)?
Figure 22-32

Problem 9.

Figure 22-33a shows two charged particles fixed in place on an x axis with separation $L$. The ratio $q_1/q_2$ of their charge magnitudes is 4.00. Figure 22-33b shows the x component $E_{\text{net},x}$ of their net electric field along the x axis just to the right of particle 2. The x axis scale is set by $x_s = 30.0$ cm. (a) At what value of $x > 0$ is $E_{\text{net},x}$ maximum? (b) If particle 2 has charge $-q_2 = -3e$, what is the value of that maximum?

Figure 22-33b

Problem 10.

Figure 22-34 shows an uneven arrangement of electrons (e) and protons (p) on a circular arc of radius $r = 2.00$ cm, with angles $\theta_1 = 30.0^\circ$, $\theta_2 = 50.0^\circ$, $\theta_3 = 30.0^\circ$, and $\theta_4 = 20.0^\circ$. What are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the net electric field produced at the center of the arc?

Figure 22-34

Problem 12.
Figure 22-35 shows a proton (p) on the central axis through a disk with a uniform charge density due to excess electrons. Three of those electrons are shown: electron \( e_c \) at the disk center and electrons \( e_s \) at opposite sides of the disk, at radius \( R \) from the center. The proton is initially at distance \( z = R = 2.00 \text{ cm} \) from the disk. At that location, what are the magnitudes of (a) the electric field \( \vec{E}_c \) due to electron \( e_c \) and (b) the net electric field \( \vec{E}_{s,\text{net}} \) due to electrons \( e_s \)? The proton is then moved to \( z = R/10.0 \). What then are the magnitudes of (c) \( \vec{E}_c \) and (d) \( \vec{E}_{s,\text{net}} \) at the proton's location? (e) From (a) and (c) we see that as the proton gets nearer to the disk, the magnitude of \( \vec{E}_c \) increases. Why does the magnitude of \( \vec{E}_{s,\text{net}} \) decrease, as we see from (b) and (d)?

**Figure 22-35** Problem 13.

**14** In Fig. 22-36, particle 1 of charge \( q_1 = -5.00q \) and particle 2 of charge \( q_2 = +2.00q \) are fixed to an \( x \) axis. (a) As a multiple of distance \( L \), at what coordinate on the axis is the net electric field of the particles zero? (b) Sketch the net electric field lines.

**Figure 22-36** Problem 14.

**15** In Fig. 22-37, the three particles are fixed in place and have charges \( q_1 = q_2 = +e \) and \( q_3 = +2e \). Distance \( a = 6.00 \text{ μm} \). What are the (a) magnitude and (b) direction of the net electric field at point \( P \) due to the particles?

**Figure 22-37** Problem 15.

**16** Figure 22-38 shows a plastic ring of radius \( R = 50.0 \text{ cm} \). Two small charged beads are on the ring: Bead 1 of charge \( +2.00 \text{ μC} \) is fixed in place at the left side; bead 2 of charge \( +6.00 \text{ μC} \) can be moved along the ring. The two beads produce a net electric field of magnitude \( E \) at the center of the ring. At what (a) positive and (b) negative value of angle \( \theta \) should bead 2 be positioned.
such that $E = 2.00 \times 10^5 \text{ N/C}$?

---

**Figure 22-38** Problem 16.

---

*Problem 16.*

Two charged beads are on the plastic ring in Fig. 22-39a. Bead 2, which is not shown, is fixed in place on the ring, which has radius $R = 60.0 \text{ cm}$. Bead 1 is initially on the $x$ axis at angle $\theta = 0^\circ$. It is then moved to the opposite side, at angle $\theta = 180^\circ$, through the first and second quadrants of the $xy$ coordinate system. Figure 22-39b gives the $x$ component of the net electric field produced at the origin by the two beads as a function of $\theta$, and Fig. 22-39c gives the $y$ component. The vertical axis scales are set by $E_{xs} = 5.0 \times 10^4 \text{ N/C}$ and $E_{ys} = -9.0 \times 10^4 \text{ N/C}$. (a) At what angle $\theta$ is bead 2 located? What are the charges of (b) bead 1 and (c) bead 2?

---

**Figure 22-39** Problem 17.

---

**sec. 22-5 The Electric Field Due to an Electric Dipole**

*Problem 18.* The electric field of an electric dipole along the dipole axis is approximated by Eqs. 22-8 and 22-9. If a binomial expansion is made of Eq. 22-7, what is the next term in the expression for the dipole's electric field along the dipole axis? That is, what is $E_{\text{next}}$ in the expression

$$E = \frac{1}{2\pi \varepsilon_0} \frac{qd}{z^3} + E_{\text{next}}?$$
Figure 22-40 shows an electric dipole. What are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the dipole's electric field at point P, located at distance \( r \gg d \)?

\[ +q \quad +q \]
\[ \quad d/2 \]
\[ \quad x \]
\[ \quad +q \]
\[ \quad d/2 \]
\[ -q \quad -q \]
\[ \quad y \]
\[ \quad \bullet \quad P \]
\[ \quad r \]

**Figure 22-40** Problem 19.

Equations 22-8 and 22-9 are approximations of the magnitude of the electric field of an electric dipole, at points along the dipole axis. Consider a point P on that axis at distance \( z = 5.00d \) from the dipole center (\( d \) is the separation distance between the particles of the dipole). Let \( E_{\text{appr}} \) be the magnitude of the field at point P as approximated by Eqs. 22-8 and 22-9. Let \( E_{\text{act}} \) be the actual magnitude. What is the ratio \( E_{\text{appr}} / E_{\text{act}} \)?

**SSM** Electric quadrupole. Figure 22-41 shows an electric quadrupole. It consists of two dipoles with dipole moments that are equal in magnitude but opposite in direction. Show that the value of \( E \) on the axis of the quadrupole for a point \( P \) a distance \( z \) from its center (assume \( z \gg d \)) is given by

\[ E = \frac{3Q}{4\pi \varepsilon_0 z^4} \]

in which \( Q (= 2qd^2) \) is known as the quadrupole moment of the charge distribution.

\[ +q \quad -q \quad +q \]
\[ \quad d \quad d \quad d \]
\[ \quad z \]
\[ \quad -p \quad +p \]

**Figure 22-41** Problem 21.

**sec. 22-6 The Electric Field Due to a Line of Charge**

**Density, density, density.** (a) A charge \( -300e \) is uniformly distributed along a circular arc of radius 4.00 cm, which subtends an angle of 40°. What is the linear charge density along the arc? (b) A charge \( -300e \) is uniformly distributed over one face of a circular disk of radius 2.00 cm. What is the surface charge density over that face? (c) A charge \( -300e \) is uniformly distributed over the surface of a sphere of radius 2.00 cm. What is the surface charge density over that surface? (d) A charge \( -300e \) is uniformly spread through the volume of a sphere of radius 2.00 cm. What is the volume charge density in that sphere?

**Figure 22-42** shows two parallel nonconducting rings with their central axes along a common line. Ring 1 has uniform charge \( q_1 \) and radius \( R \); ring 2 has uniform charge \( q_2 \) and the same radius \( R \). The rings are separated by distance \( d = 3.00R \). The
net electric field at point $P$ on the common line, at distance $R$ from ring 1, is zero. What is the ratio $q_1/q_2$?

**Figure 22-42** Problem 23.

**24** A thin nonconducting rod with a uniform distribution of positive charge $Q$ is bent into a circle of radius $R$ (Fig. 22-43). The central perpendicular axis through the ring is a $z$ axis, with the origin at the center of the ring. What is the magnitude of the electric field due to the rod at (a) $z = 0$ and (b) $z = \infty$? (c) In terms of $R$, at what positive value of $z$ is that magnitude maximum? (d) If $R = 2.00$ cm and $Q = 4.00 \mu C$, what is the maximum magnitude?

**Figure 22-43** Problem 24.

**25** Figure 22-44 shows three circular arcs centered on the origin of a coordinate system. On each arc, the uniformly distributed charge is given in terms of $Q = 2.00 \mu C$. The radii are given in terms of $R = 10.0$ cm. What are the (a) magnitude and (b) direction (relative to the positive $x$ direction) of the net electric field at the origin due to the arcs?

**Figure 22-44** Problem 25.

**26** In Fig. 22-45, a thin glass rod forms a semicircle of radius $r = 5.00$ cm. Charge is uniformly distributed along the rod, with $+q = 4.50$ pC in the upper half and $-q = -4.50$ pC in the lower half. What are the (a) magnitude and (b) direction (relative to the positive direction of the $x$ axis) of the electric field \( \vec{E} \) at $P$, the center of the semicircle?
27 In Fig. 22.46, two curved plastic rods, one of charge +q and the other of charge -q. Top of Form form a circle of radius R = 8.50 cm in an xy plane. The x axis passes through both of the connecting points, and the charge is distributed uniformly on both rods. If q = 15.0 pC, what are the (a) magnitude and (b) direction (relative to the positive direction of the x axis) of the electric field \( \vec{E} \) produced at P, the center of the circle?

28 Charge is uniformly distributed around a ring of radius R = 2.40 cm, and the resulting electric field magnitude \( E \) is measured along the ring's central axis (perpendicular to the plane of the ring). At what distance from the ring's center is \( E \) maximum?

29 Figure 22.47a shows a nonconducting rod with a uniformly distributed charge +Q. Top of Form The rod forms a half-circle with radius R and produces an electric field of magnitude \( E_{\text{arc}} \) at its center of curvature P. If the arc is collapsed to a point at distance R from P (Fig. 22.47b), by what factor is the magnitude of the electric field at P multiplied?

30 Figure 22.48 shows two concentric rings, of radii R and \( R' = 3.00R \), that lie on the same plane. Point P lies on the central z axis, at distance D = 2.00R from the center of the rings. The smaller ring has uniformly distributed charge +Q. In terms of Q, what is the uniformly distributed charge on the larger ring if the net electric field at P is zero?
Problem 30.

In Fig. 22-49, a nonconducting rod of length \( L = 8.15 \) cm has a charge \(-q = -4.23 \) fC uniformly distributed along its length. (a) What is the linear charge density of the rod? What are the (b) magnitude and (c) direction (relative to the positive direction of the \( x \) axis) of the electric field produced at point \( P \), at distance \( a = 12.0 \) cm from the rod? What is the electric field magnitude produced at distance \( a = 50 \) m by (d) the rod and (e) a particle of charge \(-q = -4.23 \) fC that replaces the rod?

![Figure 22-49](image)

Problem 31.

In Fig. 22-50, positive charge \( q = 7.81 \) pC is spread uniformly along a thin nonconducting rod of length \( L = 14.5 \) cm. What are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the electric field produced at point \( P \), at distance \( R = 6.00 \) cm from the rod along its perpendicular bisector?

![Figure 22-50](image)

Problem 32.

In Fig. 22-51, a “semi-infinite” nonconducting rod (that is, infinite in one direction only) has uniform linear charge density \( \lambda \). Show that the electric field \( \vec{E} \) at point \( P \) makes an angle of 45° with the rod and that this result is independent of the distance \( R \). (Hint: Separately find the component of \( \vec{E} \) parallel to the rod and the component perpendicular to the rod.)

![Figure 22-51](image)
sec. 22-7 The Electric Field Due to a Charged Disk

- **34** A disk of radius 2.5 cm has a surface charge density of 5.3 mC/m² on its upper face. What is the magnitude of the electric field produced by the disk at a point on its central axis at distance \( z = 12 \) cm from the disk?

- **35** At what distance along the central perpendicular axis of a uniformly charged plastic disk of radius 0.600 m is the magnitude of the electric field equal to one-half the magnitude of the field at the center of the surface of the disk?

- **36** A circular plastic disk with radius \( R = 2.00 \) cm has a uniformly distributed charge \( Q = + (2.00 \times 10^6) e \) on one face. A circular ring of width 30 \( \mu \)m is centered on that face, with the center of that width at radius \( r = 0.50 \) cm. In coulombs, what charge is contained within the width of the ring?

- **37** Suppose you design an apparatus in which a uniformly charged disk of radius \( R \) is to produce an electric field. The field magnitude is most important along the central perpendicular axis of the disk, at a point \( P \) at distance \( 2.00R \) from the disk (Fig. 22-52a). Cost analysis suggests that you switch to a ring of the same outer radius \( R \) but with inner radius \( R/2.00 \) (Fig. 22-52b). Assume that the ring will have the same surface charge density as the original disk. If you switch to the ring, by what percentage will you decrease the electric field magnitude at \( P \)?

- **38** Figure 22-53a shows a circular disk that is uniformly charged. The central \( z \) axis is perpendicular to the disk face, with the origin at the disk. Figure 22-53b gives the magnitude of the electric field along that axis in terms of the maximum magnitude \( E_m \) at the disk surface. The \( z \) axis scale is set by \( z_s = 8.0 \) cm. What is the radius of the disk?
sec. 22-8 A Point Charge in an Electric Field

• 39 In Millikan’s experiment, an oil drop of radius 1.64 μm and density 0.851 g/cm³ is suspended in chamber C (Fig. 22-14) when a downward electric field of $1.92 \times 10^5$ N/C is applied. Find the charge on the drop, in terms of $e$.

• 40 An electron with a speed of $5.00 \times 10^8$ cm/s enters an electric field of magnitude $1.00 \times 10^3$ N/C, traveling along a field line in the direction that retards its motion. (a) How far will the electron travel in the field before stopping momentarily, and (b) how much time will have elapsed? (c) If the region containing the electric field is 8.00 mm long (too short for the electron to stop within it), what fraction of the electron’s initial kinetic energy will be lost in that region?

• 41 A charged cloud system produces an electric field in the air near Earth’s surface. A particle of charge $-2.0 \times 10^{-9}$ C is acted on by a downward electrostatic force of $3.0 \times 10^{-6}$ N when placed in this field. (a) What is the magnitude of the electric field? What are the (b) magnitude and (c) direction of the electrostatic force on the proton placed in this field? (d) What is the magnitude of the gravitational force on the proton? (e) What is the ratio $F_e / F_g$ in this case?

• 42 Humid air breaks down (its molecules become ionized) in an electric field of $3.0 \times 10^6$ N/C. In that field, what is the magnitude of the electrostatic force on (a) an electron and (b) an ion with a single electron missing?

• 43 An electron is released from rest in a uniform electric field of magnitude $2.00 \times 10^4$ N/C. Calculate the acceleration of the electron. (Ignore gravitation.)

• 44 An alpha particle (the nucleus of a helium atom) has a mass of $6.64 \times 10^{-27}$ kg and a charge of $+2e$. What are the (a) magnitude and (b) direction of the electric field that will balance the gravitational force on the particle?

• 45 An electron on the axis of an electric dipole is 25 nm from the center of the dipole. What is the magnitude of the electrostatic force on the electron if the dipole moment is $3.6 \times 10^{-29}$ C · m? Assume that 25 nm is much larger than the dipole charge separation.

• 46 An electron is accelerated eastward at $1.80 \times 10^9$ m/s² by an electric field. Determine the field (a) magnitude and (b) direction.

• 47 Beams of high-speed protons can be produced in “guns” using electric fields to accelerate the protons. (a) What acceleration would a proton experience if the gun’s electric field were $2.00 \times 10^5$ N/C? (b) What speed would the proton attain if the field accelerated the proton through a distance of 1.00 cm?

• 48 In Fig. 22-54, an electron (e) is to be released from rest on the central axis of a uniformly charged disk of radius $R$. The surface charge density on the disk is +4.00 μC/m². What is the magnitude of
the electron's initial acceleration if it is released at a distance (a) \( R \), (b) \( R/100 \), and (c) \( R/1000 \) from the center of the disk? (d) Why does the acceleration magnitude increase only slightly as the release point is moved closer to the disk?

**Figure 22-54** Problem 48.

**49** A 10.0 g block with a charge of \( +8.00 \times 10^{-5} \text{ C} \) is placed in an electric field \( \vec{E} = (3000 \hat{i} - 600 \hat{j}) \text{ N} / \text{ C} \). What are the (a) magnitude and (b) direction (relative to the positive direction of the \( x \) axis) of the electrostatic force on the block? If the block is released from rest at the origin at time \( t = 0 \), what are its (c) \( x \) and (d) \( y \) coordinates at \( t = 3.00 \text{ s} \)?

**50** At some instant the velocity components of an electron moving between two charged parallel plates are \( v_x = 1.5 \times 10^5 \text{ m/s} \) and \( v_y = 3.0 \times 10^3 \text{ m/s} \). Suppose the electric field between the plates is given by \( \vec{E} = (120 \text{ N} / \text{ C}) \hat{j} \). In unit-vector notation, what are (a) the electron's acceleration in that field and (b) the electron's velocity when its \( x \) coordinate has changed by 2.0 cm?

**51** Assume that a honeybee is a sphere of diameter 1.000 cm with a charge of +45.0 pC uniformly spread over its surface. Assume also that a spherical pollen grain of diameter 40.0 \( \mu \text{m} \) is electrically held on the surface of the sphere because the bee's charge induces a charge of -1.00 pC on the near side of the sphere and a charge of +1.00 pC on the far side. (a) What is the magnitude of the net electrostatic force on the grain due to the bee? Next, assume that the bee brings the grain to a distance of 1.000 mm from the tip of a flower's stigma and that the tip is a particle of charge -45.0 pC. (b) What is the magnitude of the net electrostatic force on the grain due to the stigma? (c) Does the grain remain on the bee or does it move to the stigma?

**52** An electron enters a region of uniform electric field with an initial velocity of 40 km/s in the same direction as the electric field, which has magnitude \( E = 50 \text{ N/C} \). (a) What is the speed of the electron 1.5 ns after entering this region? (b) How far does the electron travel during the 1.5 ns interval?

**53** Two large parallel copper plates are 5.0 cm apart and have a uniform electric field between them as depicted in Fig. 22-55. An electron is released from the negative plate at the same time that a proton is released from the positive plate. Neglect the force of the particles on each other and find their distance from the positive plate when they pass each other. (Does it surprise you that you need not know the electric field to solve this problem?)
In Fig. 22-56, an electron is shot at an initial speed of $v_0 = 2.00 \times 10^6$ m/s, at angle $\theta_0 = 40.0^\circ$ from an x axis. It moves through a uniform electric field $\vec{E} = (5.00 \, \text{N/C}) \hat{j}$. A screen for detecting electrons is positioned parallel to the y axis, at distance $x = 3.00$ m. In unit-vector notation, what is the velocity of the electron when it hits the screen?

A uniform electric field exists in a region between two oppositely charged plates. An electron is released from rest at the surface of the negatively charged plate and strikes the surface of the opposite plate, 2.0 cm away, in a time $1.5 \times 10^{-8}$ s. (a) What is the speed of the electron as it strikes the second plate? (b) What is the magnitude of the electric field $E$?

A dipole consists of charges $+2e$ and $-2e$ separated by 0.78 nm. It is in an electric field of strength $3.4 \times 10^6$ N/C. Calculate the magnitude of the torque on the dipole when the dipole moment is (a) parallel to, (b) perpendicular to, and (c) antiparallel to the electric field.

An electric dipole consisting of charges of magnitude 1.50 nC separated by 6.20 $\mu$m is in an electric field of strength 1100 N/C. What are (a) the magnitude of the electric dipole moment and (b) the difference between the potential energies for dipole orientations parallel and antiparallel to $\vec{E}$?

A certain electric dipole is placed in a uniform electric field $\vec{E}$ of magnitude 20 N/C. Figure 22-57 gives the potential energy $U$ of the dipole versus the angle $\theta$ between $\vec{E}$ and the dipole moment $\vec{p}$. The vertical axis scale is set by $U_z = 100 \times 10^{-28}$ J. What is the magnitude of $\vec{p}$?
**59** How much work is required to turn an electric dipole 180° in a uniform electric field of magnitude \( E = 46.0 \, \text{N/C} \) if \( p = 3.02 \times 10^{-25} \, \text{C} \cdot \text{m} \) and the initial angle is 64°?

**60** A certain electric dipole is placed in a uniform electric field \( \vec{E} \) of magnitude 40 N/C. Figure 22-58 gives the magnitude \( \tau \) of the torque on the dipole versus the angle \( \theta \) between field \( \vec{E} \) and the dipole moment \( \vec{p} \). The vertical axis scale is set by \( \tau_s = 100 \times 10^{-28} \, \text{N} \cdot \text{m} \). What is the magnitude of \( \vec{p} \)?

**61** Find an expression for the oscillation frequency of an electric dipole of dipole moment \( \vec{p} \) and rotational inertia \( I \) for small amplitudes of oscillation about its equilibrium position in a uniform electric field of magnitude \( E \).

**Additional Problems**

**62** (a) What is the magnitude of an electron's acceleration in a uniform electric field of magnitude \( 1.40 \times 10^6 \, \text{N/C} \)? (b) How long would the electron take, starting from rest, to attain one-tenth the speed of light? (c) How far would it travel in that time?

**63** A spherical water drop 1.20 \( \mu \)m in diameter is suspended in calm air due to a downward-directed atmospheric electric field of magnitude \( E = 462 \, \text{N/C} \). (a) What is the magnitude of the gravitational force on the drop? (b) How many excess electrons does it have?

**64** Three particles, each with positive charge \( Q \), form an equilateral triangle, with each side of length \( d \). What is the magnitude of the electric field produced by the particles at the midpoint of any side?

**65** In Fig. 22-59a, a particle of charge \( +Q \) produces an electric field of magnitude \( E_{\text{part}} \) at point \( P \), at distance \( R \) from the particle. In Fig. 22-59b, that same amount of charge is spread uniformly along a circular arc that has radius \( R \) and subtends an angle \( \theta \). The charge on the arc produces an electric field of magnitude \( E_{\text{arc}} \) at its center of curvature \( P \). For what value of \( \theta \) does \( E_{\text{arc}} = 0.500E_{\text{part}} \)? (Hint: You will probably resort to a graphical solution.)
66. A proton and an electron form two corners of an equilateral triangle of side length $2.0 \times 10^{-6}$ m. What is the magnitude of the net electric field these two particles produce at the third corner?

67. A charge (uniform linear density $= 9.0$ nC/m) lies on a string that is stretched along an x axis from $x = 0$ to $x = 3.0$ m. Determine the magnitude of the electric field at $x = 4.0$ m on the x axis.

68. In Fig. 22-60, eight particles form a square in which distance $d = 2.0$ cm. The charges are $q_1 = +3e$, $q_2 = +e$, $q_3 = -5e$, $q_4 = -2e$, $q_5 = +3e$, $q_6 = +e$, $q_7 = -5e$, and $q_8 = +e$. In unit-vector notation, what is the net electric field at the square's center?

69. Two particles, each with a charge of magnitude 12 nC, are at two of the vertices of an equilateral triangle with edge length 2.0 m. What is the magnitude of the electric field at the third vertex if (a) both charges are positive and (b) one charge is positive and the other is negative?

70. In one of his experiments, Millikan observed that the following measured charges, among others, appeared at different times on a single drop:

<table>
<thead>
<tr>
<th>Charge (C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$6.563 \times 10^{-19}$</td>
</tr>
<tr>
<td>$13.13 \times 10^{-19}$</td>
</tr>
<tr>
<td>$19.71 \times 10^{-19}$</td>
</tr>
<tr>
<td>$8.204 \times 10^{-19}$</td>
</tr>
<tr>
<td>$16.48 \times 10^{-19}$</td>
</tr>
<tr>
<td>$22.89 \times 10^{-19}$</td>
</tr>
<tr>
<td>$11.50 \times 10^{-19}$</td>
</tr>
<tr>
<td>$18.08 \times 10^{-19}$</td>
</tr>
<tr>
<td>$26.13 \times 10^{-19}$</td>
</tr>
</tbody>
</table>

What value for the elementary charge $e$ can be deduced from these data?

71. A charge of 20 nC is uniformly distributed along a straight rod of length 4.0 m that is bent into a circular arc with a radius of 2.0 m. What is the magnitude of the electric field at the center of curvature of the arc?

72. An electron is constrained to the central axis of the ring of charge of radius $R$ in Fig. 22-10, with $z$
Show that the electrostatic force on the electron can cause it to oscillate through the ring center with an angular frequency
\[ \omega = \sqrt{\frac{eq}{4\pi \varepsilon_0 mR^3}}, \]
where \( q \) is the ring’s charge and \( m \) is the electron’s mass.

**73 SSM** The electric field in an \( xy \) plane produced by a positively charged particle is 7.2 \( \{4.0\hat{i} + 3.0\hat{j}\} \) N / C at the point (3.0, 3.0) cm and 100 \( \hat{i} \) N / C at the point (2.0, 0) cm. What are the (a) \( x \) and (b) \( y \) coordinates of the particle? (c) What is the charge of the particle?

**74** (a) What total (excess) charge \( q \) must the disk in Fig. 22-13 have for the electric field on the surface of the disk at its center to have magnitude \( 3.0 \times 10^6 \) N/C, the \( E \) value at which air breaks down electrically, producing sparks? Take the disk radius as 2.5 cm, and use the listing for air in Table 22-1. (b) Suppose each surface atom has an effective cross-sectional area of 0.015 nm\(^2\). How many atoms are needed to make up the disk surface? (c) The charge calculated in (a) results from some of the surface atoms having one excess electron. What fraction of these atoms must be so charged?

**75** In Fig. 22-61, particle 1 (of charge \( +1.00 \mu C \)), particle 2 (of charge \( +1.00 \mu C \)), and particle 3 (of charge \( Q \)) form an equilateral triangle of edge length \( a \). For what value of \( Q \) (both sign and magnitude) does the net electric field produced by the particles at the center of the triangle vanish?

![Figure 22-61](image)

**76** In Fig. 22-62, an electric dipole swings from an initial orientation \( i (\theta_i = 20.0^\circ) \) to a final orientation \( f (\theta_f = 20.0^\circ) \) in a uniform external electric field \( \vec{E} \). The electric dipole moment is \( 1.60 \times 10^{-27} \) C·m; the field magnitude is \( 3.00 \times 10^6 \) N/C. What is the change in the dipole’s potential energy?

![Figure 22-62](image)
A particle of charge \(-q_1\) is at the origin of an x axis. (a) At what location on the axis should a particle of charge \(-4q_1\) be placed so that the net electric field is zero at \(x = 2.0\) mm on the axis? (b) If, instead, a particle of charge \(+4q_1\) is placed at that location, what is the direction (relative to the positive direction of the x axis) of the net electric field at \(x = 2.0\) mm?

Two particles, each of positive charge \(q\), are fixed in place on a y axis, one at \(y = d\) and the other at \(y = -d\). (a) Write an expression that gives the magnitude \(E\) of the net electric field at points on the x axis given by \(x = ad\). (b) Graph \(E\) versus \(a\) for the range \(0 < a < 4\). From the graph, determine the values of \(a\) that give (c) the maximum value of \(E\) and (d) half the maximum value of \(E\).

A clock face has negative point charges \(-q, -2q, -3q, \ldots, -12q\) fixed at the positions of the corresponding numerals. The clock hands do not perturb the net field due to the point charges. At what time does the hour hand point in the same direction as the electric field vector at the center of the dial? (Hint: Use symmetry.)

Calculate the electric dipole moment of an electron and a proton 4.30 nm apart.

An electric field \(\vec{E}\) with an average magnitude of about 150 N/C points downward in the atmosphere near Earth's surface. We wish to “float” a sulfur sphere weighing 4.4 N in this field by charging the sphere. (a) What charge (both sign and magnitude) must be used? (b) Why is the experiment impractical?

A circular rod has a radius of curvature \(R = 9.00\) cm and a uniformly distributed positive charge \(Q = 6.25\) pC and subtends an angle \(\theta = 2.40\) rad. What is the magnitude of the electric field that \(Q\) produces at the center of curvature?

An electric dipole with dipole moment \(\vec{p} = (3.00\hat{i} + 4.00\hat{j})(1.24 \times 10^{-30}\text{C} \cdot \text{m})\) is in an electric field \(\vec{E} = (4000 \text{ N} / \text{C})\hat{i}\). (a) What is the potential energy of the electric dipole? (b) What is the torque acting on it? (c) If an external agent turns the dipole until its electric dipole moment is \(\vec{p} = (-4.00\hat{i} + 3.00\hat{j})(1.24 \times 10^{-30}\text{C} \cdot \text{m})\), how much work is done by the agent?

In Fig. 22-63, a uniform, upward electric field \(\vec{E}\) of magnitude \(2.00 \times 10^3\) N/C has been set up between two horizontal plates by charging the lower plate positively and the upper plate negatively. The plates have length \(L = 10.0\) cm and separation \(d = 2.00\) cm. An electron is then shot between the plates from the left edge of the lower plate. The initial velocity \(\vec{v}\) of the electron makes an angle \(\theta = 45.0^\circ\) with the lower plate and has a magnitude of \(6.00 \times 10^6\) m/s. (a) Will the electron strike one of the plates? (b) If so, which plate and how far horizontally from the left edge will the electron strike?
For the data of Problem 70, assume that the charge \( q \) on the drop is given by \( q = ne \), where \( n \) is an integer and \( e \) is the elementary charge. (a) Find \( n \) for each given value of \( q \). (b) Do a linear regression fit of the values of \( q \) versus the values of \( n \) and then use that fit to find \( e \).

In Fig. 22-61, particle 1 (of charge +2.00 pC), particle 2 (of charge -2.00 pC), and particle 3 (of charge +5.00 pC) form an equilateral triangle of edge length \( a = 9.50 \) cm. (a) Relative to the positive direction of the \( x \) axis, determine the direction of the force \( \vec{F}_3 \) on particle 3 due to the other particles by sketching electric field lines of the other particles. (b) Calculate the magnitude of \( \vec{F}_3 \).

In Fig. 22-64, particle 1 of charge \( q_1 = 1.00 \) pC and particle 2 of charge \( q_2 = -2.00 \) pC are fixed at a distance \( d = 5.00 \) cm apart. In unit-vector notation, what is the net electric field at points (a) \( A \), (b) \( B \), and (c) \( C \)? (d) Sketch the electric field lines.

In Fig. 22-8, let both charges be positive. Assuming \( z \gg d \), show that \( E \) at point \( P \) in that figure is then given by

\[
E = \frac{1}{4\pi \varepsilon_0} \frac{2q}{z^2}.
\]
